DM545/DM871 Linear and Integer Programming

Lecture 7 Revised Simplex Method

Marco Chiarandini

Department of Mathematics & Computer Science University of Southern Denmark

Outline

1. Revised Simplex Method

2. Efficiency Issues

Motivation

Complexity of single pivot operation in standard simplex:

- entering variable O(n)
- leaving variable O(m)
- updating the tableau O(mn)

Problems with this:

- Time: we are doing operations that are not actually needed
 Space: we need to store the whole tableau: O(mn) floating point numbers
- Most problems have sparse matrices (many zeros) sparse matrices are typically handled efficiently the standard simplex has the 'Fill in' effect: sparse matrices are lost
- accumulation of Floating Point Errors over the iterations

Outline

1. Revised Simplex Method

2. Efficiency Issue:

Revised Simplex Method

Several ways to improve wrt pitfalls in the previous slide, requires matrix description of the simplex.

$$\max \sum_{j=1}^{n} c_j x_j$$

$$\sum_{j=1}^{n} a_{ij} x_j \le b_i \ i = 1..m$$

$$x_j \ge 0 \ j = 1..n$$

$$\max \mathbf{c}^{\mathsf{T}} \mathbf{x} \qquad \max \{\mathbf{c}^{\mathsf{T}} \mathbf{x} \mid A \mathbf{x} = \mathbf{b}, \mathbf{x} \ge 0\}$$

$$\mathbf{x} \ge 0$$

$$A \in \mathbb{R}^{m \times (n+m)}$$

$$\mathbf{c} \in \mathbb{R}^{(n+m)}, \mathbf{b} \in \mathbb{R}^m, \mathbf{x} \in \mathbb{R}^{n+m}$$

At each iteration the simplex moves from a basic feasible solution to another.

For each basic feasible solution:

•
$$B = \{1 \dots m\}$$
 basis

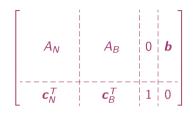

•
$$N = \{m+1...m+n\}$$

•
$$A_B = [\mathbf{a}_1 \dots \mathbf{a}_m]$$
 basis matrix

$$\bullet \ A_N = [\mathbf{a}_{m+1} \dots \mathbf{a}_{m+n}]$$

•
$$x_N = 0$$

•
$$\mathbf{x}_B \geq 0$$

$$A\mathbf{x} = A_N \mathbf{x}_N + A_B \mathbf{x}_B = \mathbf{b}$$

 $A_B \mathbf{x}_B = \mathbf{b} - A_N \mathbf{x}_N$

Basic feasible solution \iff A_B is non-singular

$$\mathbf{x}_B = A_B^{-1}\mathbf{b} - A_B^{-1}A_N\mathbf{x}_N$$

6

for the objective function:

$$z = \boldsymbol{c}^T \boldsymbol{x} = \boldsymbol{c}_B^T \boldsymbol{x}_B + \boldsymbol{c}_N^T \boldsymbol{x}_N$$

Substituting for x_B from above:

$$z = \boldsymbol{c}_{B}^{T}(A_{B}^{-1}\boldsymbol{b} - A_{B}^{-1}A_{N}\boldsymbol{x}_{N}) + \boldsymbol{c}_{N}^{T}\boldsymbol{x}_{N} =$$

$$= \boldsymbol{c}_{B}^{T}A_{B}^{-1}\boldsymbol{b} + (\boldsymbol{c}_{N}^{T} - \boldsymbol{c}_{B}^{T}A_{B}^{-1}A_{N})\boldsymbol{x}_{N}$$

Collecting together:

$$egin{aligned} oldsymbol{x}_B &= A_B^{-1} oldsymbol{b} - A_B^{-1} A_N oldsymbol{x}_N \ z &= oldsymbol{c}_B^T A_B^{-1} oldsymbol{b} + (oldsymbol{c}_N^T - oldsymbol{c}_B^T \underbrace{A_B^{-1} A_N}_{ar{A}}) oldsymbol{x}_N \end{aligned}$$

In tableau form, for a basic feasible solution corresponding to B we have:

$$\begin{bmatrix} A_B^{-1}A_N & I & 0 & A_B^{-1}\mathbf{b} \\ \hline c_N^T - c_B^T A_B^{-1}A_N & 0 & 1 & -c_B^T A_B^{-1}\mathbf{b} \end{bmatrix}$$

We do not need to compute all elements of $\bar{\cal A}$

Example

$$\begin{array}{ccc} \max & x_1 + x_2 \\ -x_1 + x_2 \leq 1 \\ x_1 & \leq 3 \\ & x_2 \leq 2 \\ & x_1, x_2 \geq 0 \end{array}$$

Initial tableau

$$\begin{vmatrix} x1 & x2 & x3 & x4 & x5 & -z & b \\ -1 & 1 & 1 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 & 0 & 0 & 3 \\ -0 & 1 & 0 & 0 & 0 & 1 & 0 & 2 \\ -1 & 1 & 0 & 0 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ \end{vmatrix}$$

After two iterations

Basic variables x_1, x_2, x_4 . Non basic: x_3, x_5 . From the initial tableau:

$$A_{B} = \begin{bmatrix} -1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \quad A_{N} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{bmatrix} \quad x_{B} = \begin{bmatrix} x_{1} \\ x_{2} \\ x_{4} \end{bmatrix} \quad x_{N} = \begin{bmatrix} x_{3} \\ x_{5} \end{bmatrix}$$

$$c_B^T = \begin{bmatrix} 1 \ 1 \ 0 \end{bmatrix} \quad c_N^T = \begin{bmatrix} 0 \ 0 \end{bmatrix}$$

• Entering variable:

in std. we look at tableau, in revised we need to compute: $\boldsymbol{c}_N^T - \boldsymbol{c}_B^T A_R^{-1} A_N$

- 1. find $\mathbf{y}^T = \mathbf{c}_B^T A_B^{-1}$ (by solving $\mathbf{y}^T A_B = \mathbf{c}_B^T$, the latter can be done more efficiently)
- 2. calculate $\mathbf{c}_N^T \mathbf{y}^T A_N$

•

Step 1:

$$\begin{bmatrix} y_1 & y_2 & y_3 \end{bmatrix} \begin{bmatrix} -1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 1 & 0 \end{bmatrix} \begin{bmatrix} -1 & 0 & 1 \\ 0 & 0 & 1 \\ 1 & 1 & -1 \end{bmatrix} = \begin{bmatrix} -1 & 0 & 2 \end{bmatrix}$$

Step 2:

$$\begin{bmatrix} 0 & 0 \end{bmatrix} - \begin{bmatrix} -1 & 0 & 2 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & -2 \end{bmatrix}$$

(Note that they can be computed individually: $c_j - \mathbf{y}^T \mathbf{a}_j > 0$) Let's take the first we encounter x_3

$$\mathbf{y}^T A_B = \mathbf{c}_B^T$$

$$\boldsymbol{c}_{B}^{T}A_{B}^{-1}=\boldsymbol{y}^{T}$$

$$\boldsymbol{c}_N^T - \boldsymbol{y}^T A_N$$

Leaving variable

we increase variable by largest feasible amount θ

R1:
$$x_1 - x_3 + x_5 = 1$$

R2: $x_2 + x_5 = 2$

R3:
$$-x_3 + x_4 - x_5 = 2$$

$$x_1 = 1 + x_3 \ge 0$$

 $x_2 = 2 \ge 0$
 $x_4 = 2 - x_3 > 0$

$$\mathbf{x}_B = \mathbf{x}_B^* - A_B^{-1} A_N \mathbf{x}_N$$

 $\mathbf{x}_B = \mathbf{x}_B^* - \mathbf{d}\theta$

d is the column of $A_R^{-1}A_N$ that corresponds to the entering variable, ie, $d = A_B^{-1} a$ where a is the entering column

3. Find θ such that \mathbf{x}_{R} stays positive: Find $\mathbf{d} = A_B^{-1} \mathbf{a}$ (by solving $A_B \mathbf{d} = \mathbf{a}$)

Step 3:

$$\begin{bmatrix} d_1 \\ d_2 \\ d_3 \end{bmatrix} = \begin{bmatrix} -1 & 0 & 1 \\ 0 & 0 & 1 \\ 1 & 1 & -1 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} \implies \mathbf{d} = \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} \implies \mathbf{x}_B = \begin{bmatrix} 1 \\ 2 \\ 2 \end{bmatrix} - \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} \theta \ge 0$$

$$2-\theta \ge 0 \implies \theta \le 2 \rightsquigarrow x_4$$
 leaves

• So far we have done computations, but now we save the pivoting update. The update of A_B is done by replacing the leaving column by the entering column

$$x_{B}^{*} = \begin{bmatrix} x_{1} - d_{1}\theta \\ x_{2} - d_{2}\theta \\ \theta \end{bmatrix} = \begin{bmatrix} 3 \\ 2 \\ 2 \end{bmatrix} \qquad A_{B} = \begin{bmatrix} -1 & 1 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$$

- Many implementations depending on how $\mathbf{y}^T A_B = \mathbf{c}_B^T$ and $A_B \mathbf{d} = \mathbf{a}$ are solved. They are in fact solved from scratch.
- many operations saved especially if many variables!
- special ways to call the matrix A from memory
- better control over numerical issues since A_B^{-1} can be recomputed.

Revised Simplex Method Efficiency Issues

Outline

1. Revised Simplex Method

2. Efficiency Issues

Solving the two Systems of Equations

 $A_{BX} = b$ solved without computing A_{B}^{-1} (costly and likely to introduce numerical inaccuracy)

Recall how the inverse is computed:

For a 2×2 matrix

the matrix inverse is

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

$$A^{-1} = \frac{1}{|A|} \begin{bmatrix} d & -c \\ -b & a \end{bmatrix}^{T} = \frac{1}{ad - bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$$

For a 3×3 matrix

the matrix inverse is

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$$

$$A^{-1} = \frac{1}{|A|} \begin{bmatrix} +\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} - \begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} + \begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix} \end{bmatrix}^{T}$$

$$A^{-1} = \frac{1}{|A|} \begin{bmatrix} -\begin{vmatrix} a_{12} & a_{13} \\ a_{32} & a_{33} \end{vmatrix} + \begin{vmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{vmatrix} - \begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix} + \begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix} - \begin{vmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{vmatrix} + \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} \end{bmatrix}$$

Eta Factorization of the Basis

Let $B := A_B$, kth iteration B_k be the matrix with col p differing from B_{k-1} Column p is the a column appearing in $B_{k-1}d = a$ solved at 3) Hence:

$$B_{\nu} = B_{\nu-1} E_{\nu}$$

 E_k is the eta matrix differing from id. matrix in only one column, which is set equal to d

$$\begin{bmatrix} -1 & 1 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix} = \begin{bmatrix} -1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 1 & 0 \\ & 1 \end{bmatrix}$$

No matter how we solve $\mathbf{y}^T B_{k-1} = \mathbf{c}_B^T$ and $B_{k-1} \mathbf{d} = \mathbf{a}$, their update always relays on $B_k = B_{k-1} E_k$ with E_k available. Plus when initial basis by slack variable $B_0 = I$ and $B_1 = E_1, B_2 = E_1 E_2 \cdots$:

$$B_k = E_1 E_2 \dots E_k$$
 eta factorization

$$((((y^{T}E_{1})E_{2})E_{3})\cdots)E_{k} = c_{B}^{T}, \qquad u^{T}E_{4} = c_{B}^{T}, \ v^{T}E_{3} = u^{T}, \ w^{T}E_{2} = v^{T}, \ y^{T}E_{1} = w^{T}$$

$$(E_{1}(E_{2}\cdots E_{k}d)) = a, \qquad E_{1}u = a, \ E_{2}v = u, \ E_{3}w = v, \ E_{4}d = w$$

Exercise

Solve the systems $\mathbf{y}^T E_1 E_2 E_3 E_4 = [1\ 2\ 3]$ and $E_1 E_2 E_3 E_4 \mathbf{d} = [1\ 2\ 3]^T$ with

$$E_1 = \begin{bmatrix} 1 & 3 & 0 \\ 0 & 0.5 & 0 \\ 0 & 4 & 1 \end{bmatrix} \qquad E_2 = \begin{bmatrix} 2 & 0 & 0 \\ 1 & 1 & 0 \\ 4 & 0 & 1 \end{bmatrix} \qquad E_3 = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 1 \end{bmatrix} \qquad E_4 = \begin{bmatrix} -0.5 & 0 & 0 \\ 3 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix}$$

We use backward transformation and solve the sequence of linear systems:

$$u^{T}E_{4} = [1 \ 2 \ 3], \quad v^{T}E_{3} = u^{T}, \quad w^{T}E_{2} = v^{T}, \quad y^{T}E_{1} = w^{T}$$

$$\boldsymbol{u}^T \begin{bmatrix} -0.5 & 0 & 0 \\ 3 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} = [1, 2, 3]$$

Since the eta matrices have always one 1 in two columns then the solution can be read up easily. From the third column we find $u_3 = 3$. From the second column, we find $u_2 = 2$. Substituting in the first column, we find $-0.5u_1 + 3 \cdot 2 + 1 \cdot 3 = 1$, which yields $u_1 = 16$. The next syestem is:

$$\mathbf{v}^T \begin{vmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 1 \end{vmatrix} = [16, 2, 3]$$

From the first column we get $v_1 = 16$, from the second column $v_2 = 2$ from the last column $v_1 + 3v_2 + v_3 = 3$, which yields $v_3 = -19$. The next:

$$\mathbf{w}^T \begin{vmatrix} 2 & 0 & 0 \\ 1 & 1 & 0 \\ 4 & 0 & 1 \end{vmatrix} = [16, 2, -19]$$

. . .

- Solving $\mathbf{y}^T B_k = \mathbf{c}_B^T$ also called backward transformation (BTRAN)
- Solving $B_k d = a$ also called forward transformation (FTRAN)
- E_i matrices can be stored by only storing the column and the position
- If sparse columns then can be stored in compact mode, ie only nonzero values and their indices

More on LP

- Tableau method is unstable: computational errors may accumulate. Revised method has a natural control mechanism: we can recompute A_B^{-1} at any time
- Commercial and freeware solvers differ from the way the systems $\mathbf{y}^T A_B = \mathbf{c}_B^T$ and $A_B \mathbf{d} = \mathbf{a}$ are resolved

Efficient Implementations

- Dual simplex with steepest descent (largest increase)
- Linear Algebra:
 - Dynamic LU-factorization using Markowitz threshold pivoting (Suhl and Suhl, 1990)
 - sparse linear systems: Typically these systems take as input a vector with a very small number of nonzero entries and output a vector with only a few additional nonzeros.
- Presolve, ie problem reductions: removal of redundant constraints, fixed variables, and other extraneous model elements.
- dealing with degeneracy, stalling (long sequences of degenerate pivots), and cycling:
 - bound-shifting (Paula Harris, 1974)
 - Hybrid Pricing (variable selection): start with partial pricing, then switch to devex (approximate steepest-edge, Harris, 1974)
- A model that might have taken a year to solve 10 years ago can now solve in less than 30 seconds (Bixby, 2002).

Further topics in LP

- Ellipsoid method: cannot compete in practice but polynomial time (Khachyian, 1979)
- Interior point algorithm(s) (Karmarkar, 1984) competitive with simplex and polynomial in some versions
 - iterate through points interior to the feasibility region
 - because of patents reasons, also known as barrier algorithm
 - one single iteration is computationally more intensive than the simplex
 - particularly competitive in presence of many constraints (eg, for m = 10,000 may need less than 100 iterations)
 - bad for post-optimality analysis \leadsto crossover algorithm to convert a sol of barrier method into a basic feasible solutions for the simplex
 - usually fastest for large, difficult models but numerically sensitive.
- Lagrangian relaxation
- Column generation
- Decomposition methods:
 - Dantzig Wolfe decomposition
 - Benders decomposition

Interior Point Algorithm

- 1. Start at an interior point of the feasible region
- 2. Move in a direction that improves the objective function value at the fastest possible rate
- 3. Transform the feasible region to place the current point at the center of it

How Large Problems Can We Solve?

•	Very large model		
	Rows	Columns	Nonzeros
Original size	5034171	7365337	25596099
After presolve	1296075	2910559	10339042

Solution times were as follows:

Very large model—solution times						
		Algorithm				
	Version	Barrier	Dual	Primal		
	CPLEX 5.0	8642.6	350000.0	71039.7		
	CPLEX 7.1	5642.6	6413.1	1880.0
